| <p>(57) Abstract</p> <p>A system (10) and method of evidencing postage payment include a local postage printing system (20, 22) requesting to a remote data metering center (30) for the generation of postage evidencing information (220, 320). The request includes a postage amount to be printed on a mail piece. The remote data metering center (30) determines a postal origin (220, 320) corresponding to the request for postage evidencing information (220, 320), then accounts for the postage amount in a general account (220, 320) corresponding to the local postage printing system (20, 22) and in a payment account corresponding to the determined postal origin (240, 340). The remote metering center (30) generates postage evidencing information (220, 320) in response to the request. The postal evidencing information includes a digital token and the determined postal origin (220, 320). The remote data metering center (30) sends the postage evidencing information to the local postage printing system (20, 22) which prints the postage evidencing information and the determined postal origin on the mail piece.</p> |  |  |   |

**VIRTUAL POSTAGE METER WITH MULTIPLE ORIGINS OF DEPOSIT**

This is a continuation-in-part application of U.S. Provisional Patent Application Serial Number 60/049,518, filed June 13, 1997 and assigned to the  
5 assignee of the present invention.

**Technical Field**

The present invention relates generally to a postage metering system and method for evidencing postage payment in an open system and, more particularly, to a postage metering system and method for evidencing postage  
10 payment in a virtual meter configuration.

**Related Applications**

The present application is related to the following International Patent Applications Serial Nos. (Attorney Docket Nos. E-731, E-734, E-736 and E-738), all filed concurrently herewith, and U.S. Patent Application Serial Number  
15 08/993,310, filed December 18, 1997, all being assigned to the assignee of the present invention.

**Background Art**

Postage metering systems have been developed which employ encrypted information that is printed on a mailpiece as part of an indicium evidencing  
20 postage payment. The encrypted information includes a postage value for the mailpiece combined with other postal data that relate to the mailpiece and the postage meter printing the indicium. The encrypted information, typically referred to as a digital token or a digital signature, authenticates and protects the integrity of information, including the postage value, imprinted on the mailpiece  
25 for later verification of postage payment. Since the digital token incorporates encrypted information relating to the evidencing of postage payment, altering the printed information in an indicium is detectable by standard verification procedures. Examples of systems that generate and print such indicium are described in U.S. Patent Numbers 4,725,718, 4,757,537, 4,775,246 and  
30 4,873,645, each assigned to the assignee of the present invention.

Presently, there are two postage metering device types: a closed system and an open system. In a closed system, the system functionality is solely

dedicated to metering activity. Examples of closed system metering devices, also referred to as postage evidencing devices, include conventional digital and analog (mechanical and electronic) postage meters wherein a dedicated printer is securely coupled to a metering or accounting function. In a closed system,  
5 typically the printer is securely coupled and dedicated to the meter, and printing evidence of postage cannot take place without accounting for the evidence of postage. In an open system, the printer is not dedicated to the metering activity, freeing system functionality for multiple and diverse uses in addition to the metering activity. Examples of open system metering devices include personal  
10 computer (PC) based devices with single/multi-tasking operating systems, multi-user applications and digital printers. An open system metering device is a postage evidencing device with a non-dedicated printer that is not securely coupled to a secure accounting module. An open system indicium printed by the non-dedicated printer is made secure by including addressee information in the  
15 encrypted evidence of postage printed on the mailpiece for subsequent verification. See U.S. Patent Numbers 4,725,718 and 4,831,555, each assigned to the assignee of the present invention.

The United States Postal Service ("USPS") has proposed an Information-Based Indicia Program ("IBIP"), which is a distributed trusted system to retrofit  
20 and augment existing postage meters using new evidence of postage payment known as information-based indicia. The program relies on digital signature techniques to produce for each envelope an indicium whose origin can be authenticated and content cannot be modified. IBIP is expected to support new methods of applying postage in addition to the current approach, which typically  
25 relies on a postage meter to mechanically print indicia on mailpieces. IBIP requires printing a large, high density, two-dimensional ("2-D") bar code on a mailpiece. The 2-D bar code encodes information and is signed with a digital signature.

The USPS has published draft specifications for IBIP. The  
30 INFORMATION BASED INDICIA PROGRAM (IBIP) INDICIUM SPECIFICATION, dated June 13, 1996, and revised July 23, 1997, ("IBIP Indicium Specification") defines the proposed requirements for a new indicium that will be applied to mail being created using IBIP. The INFORMATION

BASED INDICIA PROGRAM POSTAL SECURITY DEVICE SPECIFICATION, dated June 13, 1996, and revised July 23, 1997, ("IBIP PSD Specification") defines the proposed requirements for a Postal Security Device ("PSD"), which is a secure processor-based accounting device that dispenses and accounts for postal value stored therein to support the creation of a new "information based" postage postmark or indicium that will be applied to mail being processed using IBIP. The INFORMATION BASED INDICIA PROGRAM HOST SYSTEM SPECIFICATION, dated October 9, 1996, defines the proposed requirements for a host system element of IBIP ("IBIP Host Specification"). IBIP includes interfacing user, postal and vendor infrastructures which are the system elements of the program. The INFORMATION BASED INDICIA PROGRAM KEY MANAGEMENT PLAN, dated April 25, 1997, defines the generation, distribution, use and replacement of the cryptographic keys used by the USPS product/service provider and PSDs ("IBIP KMS Specification"). The specifications are collectively referred to herein as the "IBIP Specifications".

The IBIP Specifications define a stand-alone open metering system, referred to herein as a PC Meter comprising a PSD coupled to a personal computer ("PC") which operates as a host system with a printer coupled thereto ("Host PC"). The Host PC runs the metering application software and associated libraries (collectively referred to herein as "Host Applications") and communicates with one or more attached PSDs. The PC Meter can only access PSDs coupled to the Host PC. There is no remote PSD access for the PC Meter.

The PC Meter processes transactions for dispensing postage, registration and refill on the Host PC. Processing is performed locally between the Host PC and the PSD coupled thereto. Connections to a Data Center, for example for registration and refill transactions, are made locally from the Host PC through a local or network modem/internet connection. Accounting for debits and credits to the PSD is also performed locally, logging the transactions on the Host PC. The Host PC may accommodate more than one PSD, for example supporting one PSD per serial port. Several applications programs running on the Host PC, such as a word processor or an envelope designer, may access the Host Applications.

The IBIP Specifications do not address an IBIP open metering system on a network environment. However, the specifications do not prohibit such a network-based system. Generally, in a network environment a network Server PC controls remote printing requested by a Client PC on the network. Of course,  
5 the Client PC controls any local printing.

One version of a network metering system, referred to herein as a "Virtual Meter", has many Host PCs without any PSDs coupled thereto. The Host PCs run Host Applications, but all PSD functions are performed on Server(s) located at a Data Center. The PSD functions at the Data Center may be performed in a  
10 secure device attached to a computer at the Data Center, or may be performed in the computer itself. The Host PCs must connect with the Data Center to process transactions such as postage dispensing, meter registration, or meter refills. Transactions are requested by the Host PC and sent to the Data Center for remote processing. The transactions are processed centrally at the Data  
15 Center and the results are returned to the Host PC. Accounting for funds and transaction processing are centralized at the Data Center. See, for example, U.S. Patent Numbers 5,454,038 and 4,873,645, which are assigned to the assignee of the present invention. The Virtual Meter does not conform to all the current requirements of the IBIP Specifications. In particular, the IBIP  
20 Specifications do not permit PSD functions to be performed at the Data Center.

Heretofore, each metering device or accounting unit of a postage metering system has had a single origin of deposit, i.e. has been registered at a single post office. The postage funds stored in each metering device has been credited (deposited) for the account of the single post office, which is expected to  
25 be handling all mailpieces containing indicia printed by the metering device registered thereto. Thus, for companies or mailrooms requiring different origins of deposit for processing mailpieces, multiple meters have been needed to achieve such multiple origins of deposit. For example, while most meters in a mailroom in Shelton, Connecticut may be configured to evidence postage on  
30 mailpieces to be deposited in the Post Office in Shelton, Connecticut, other meters may be configured to evidence postage on mailpieces to be deposited at different origins of deposit, such as New Haven, Connecticut, which may be open later than the Shelton Post Office.

It is the current practice for a mailer who wishes to deposit mail in several post offices to have a separate meter for each post office. Sufficient funds must be placed in each meter to pay postage for mail deposited at the corresponding post office. If the meters use a conventional meter refill process, such as the 5 Postage By Phone® service provided by Pitney Bowes Inc. of Stamford, Connecticut, then the mailer must make separate refill calls for each meter. Further, once the funds are placed in a meter, they cannot easily be withdrawn or transferred to another meter. This presents difficulties for mailers who do not necessarily know in advance how much mail they wish to deposit at each post 10 office.

Various Posts, including the United States Postal Service (USPS), are now considering the viability of a virtual postage metering system. One problem presented by a virtual postage metering system is that it is easily transportable because the metering device is not local to the mailer. For example, a travelling 15 mailer using a notebook computer with Host Applications may desire sending mail from the various locations. However, the current zip deposit requirements of the USPS do not allow such movement of the metering process. Once a virtual meter arrangement is configured for an individual or a company for an origin of deposit, such transporting of the virtual postage metering system would 20 violate current USPS regulations.

#### Disclosure of the Invention

It has been determined that a virtual postage metering system provides benefits that are not available under conventional postage payment systems. For the Posts, a virtual postage metering system provides central management 25 of all postage without the need to manage physical meters or PSDs. A further benefit is the opportunity to directly associate a mailer to each mailpiece as opposed to each reset. For mailers, no metering hardware, i.e. postage meter or PSD, is needed. Nor do mailers need to maintain current lists of valid addresses, such as with purchased CD-ROMs. Mailers can acquire postage on 30 an as-needed basis. Finally, meter vendors do not have to keep track of physical meters. A virtual postage metering system eliminates stolen or relocated meter problems, and simplifies meter management in general.

It has been found that an accounting process can be implemented in a postage metering device that provides simultaneous registration of the postage metering device at several different post offices. Related U.S. Patent Application Serial Number 08/993,310, filed December 18, 1997, and assigned to the assignee of the present invention, discloses a system and method whereby the postage metering device can be configured with multiple origins of deposit. The system includes a postal security device (PSD) coupled to a printer module. The PSD includes a first processor, secure accounting module, value storage module and digital signature module. The value storage module includes total postal value information and an origin postal value for each of a plurality of postal origins, wherein the PSD is authorized to dispense evidence of postage payment for each of the postal origins. The PSD performs accounting for each postage evidencing transaction. The accounting includes debiting the total postal value and incrementing one of the origin of postal values corresponding to the postage evidencing transaction. The PSD is registered at each post office corresponding to each of the plurality of postal origins. The method includes selecting one of the postal origins in the accounting module, deducting a requested postal value from a total postal value stored as a general account in the accounting module, adding the requested postal value to a sub-register corresponding to the selected postal origin in the accounting module, generating evidence of postage payment and printing the requested evidence of postage payment and the selected postal origin on the mailpiece. The evidence of postage payment includes a digital token which is an encrypted number generated using information that includes a requested postal value and the selected postal origin.

U.S. Patent Application Serial Number 08/993,310 is hereby incorporated in its entirety by reference.

Typically, a descending register in the postage metering device is credited for an amount of postage funds during postage refill for the postage metering device. In accordance with previously noted U.S. Patent Application Serial Number 08/993,310, the postage metering device also includes a plurality of sub-registers representing one of the several different post offices to which the postage metering device is authorized to use as an origin of deposit. For each transaction, when the descending register is debited for an amount of postage

one of the sub-registers is incremented for the same amount for transactions associated with its origin of deposit. At the next postage refill transaction for the postage metering device the total internal transfers to each local post office sub-registers are reported to the refill Data Center, which reports the same to the  
5 Postal Service. The Postal Service may then account postage refill funds transfer to the appropriate post office. When franking each mailpiece, the postage metering device prints an origination postal code corresponding to an appropriate post office as part of a digital indicium printed on the mailpiece.

In the present invention, the virtual postage metering system includes a  
10 Data Center configured with at least one postage metering account (PSA) associated with each mailer licensed under the virtual postage security system. The PSA includes a plurality of sub-registers associated with a plurality of origins of deposits. The sub-registers may be pre-authorized accounts representing origins of deposit from which the mailer is authorized to deposit mail, or may be  
15 accounts created each time a mailer chooses to deposit mail from a new origin of deposit. When the mailer requests postage for a mailpiece, for example, through the mailer's personal computer, the Data Center performs funds accounting and digital token calculations using a mailer's PSA. The digital token includes PSA identification as part of the encrypted information. The Data  
20 Center determines the origin of deposit based on the location from which the mailer initiates the request for postage, then performs the accounting in the PSA and the appropriate sub-register, and then generates a token which is then sent to the mailer to be printed on the mailpiece.

The PSA may be a debit account using a refill process similar to that used  
25 for traditional meters. In the alternative, the PSA can be a real time payment account that charges postage to a pre-authorized credit account of the mailer. In the preferred embodiment, the Data Center simultaneously charges a mailer's credit card when the token is generated and accounts for the postage amount in the appropriate sub-register for each origin of deposit so that the proper postal  
30 accounts can be credited for the postage issued.

Several benefits are realized from the present invention. One such benefit relates to the postal regulations requiring that the postage printed on a metered mailpiece must be obtained from a meter licensed from the local post

office at which the mailpiece is deposited for mailing, commonly referred to as "origin of deposit" or "domain". With a PSA at a Data Center and a plurality of sub accounts associated with the PSA, a mailer is not limited to a single origin of deposit or domain. For example, while some mailers may be willing to limit use  
5 of the virtual postage metering system to deposit their mailpieces in a single origin of deposit near their workplace, other mailers may desire to deposit their mailpieces at different origins of deposit. For example, a mailer may be travelling with a notebook computer with virtual postage metering system software that would allow access to the Data Center from location associated  
10 with other origins of deposit. The present invention provides each mailer with the ability to access his or her PSA at the Data Center from any such locations and to obtain evidence of postage payment that can be printed on the mailpiece and mailed from any of such locations.

The present invention provides a system and method of evidencing postage payment which includes a local postage printing system requesting to a remote data metering center for the generation of postage evidencing. The request includes a postage amount to be printed on a mailpiece. The remote data metering center determines a postal origin corresponding to the request for postage evidencing, then accounts for the postage amount in a general account  
15 corresponding to the local postage printing system and in a payment account corresponding to the determined postal origin. The remote data metering center generates postage evidence in response to the request. The postage evidence includes a digital token and the determined postal origin. The remote data metering center sends the postage evidence to the local postage printing system  
20 which prints the postage evidence and the determined postal origin on the mailpiece.  
25

#### Brief Description of the Drawings

The above and other objects and advantages of the present invention will be apparent upon consideration of the following detailed description, taken in conjunction with accompanying drawings, in which like reference characters  
30 refer to like parts throughout, and in which:

Fig. 1 is a block diagram of a system for dispensing postage embodying the principles of the present invention;

Fig. 2 is a block diagram of the Data Center Database for virtual postage metering system with multiple origins of deposit for each account;

5 Fig. 3 is a flow chart of the process for trickle charge method for accounting and distributing funds to multiple origins of deposit in accordance with the present invention; and

Fig 4 is a flow chart of a prepayment method for accounting and distributing funds to multiple origins of deposit.

10

#### Best Mode for Carrying Out the Invention

In describing the present invention, reference is made to the drawings, wherein there is seen in Fig. 1, a virtual postage metering system, generally designated 10. The virtual postage metering system 10 includes a plurality (only one is shown) of personal computer (PC) systems, generally designated 20, 15 each having access to a printer 22 for printing evidence of postage on an envelope or label. PC 20 is connected with a transaction processing Data Center 30 that performs postal accounting and evidencing of postage. The virtual postage metering system 10 allows each mailer to use a conventional PC to remotely obtain evidence of postage payment on an as needed basis. Unlike 20 conventional postage metering systems, virtual postage metering system 10 does not include any meter hardware located at the mailer's site. Nor are any postal funds stored at the mailer's site. All the metering and accounting of funds occur at Data Center 30 using functional software and database records representing the mailer's "postage meter". The accounting method for the virtual 25 postage metering system 10 may be a conventional prepayment or post-payment system. However, the preferred embodiment of the present invention is a real-time payment method in which the amount of a transaction is charged to a mailer's credit card account when the transaction occurs. This method is referred to herein as a "trickle charge" postage payment, because the mailer 30 does not pay for postage for a mailpiece until the mailer is ready to print the mailpiece.

In the virtual postage metering system, a "meter" vendor, such as Pitney Bowes Inc., provides the mailer with client software that runs on PC 20. The client software initiates communications with Data Center 30 which performs metering transactions to evidence postage for single mailpieces or batches of 5 mailpieces. In the preferred embodiment, the client software establishes a connection to the Data Center, and requests postage by providing postal information relating to the requested transactions, such as postage amount, addressee information and (optionally) the origin of deposit for each mailpiece. Data Center 30 receives the postal information, determines the origin zip for the 10 mailpiece(s), performs accounting functions and generates an encrypted evidence of postage payment, such as a token or digital signature, and sends indicium information including the token, to PC 20. PC 20 receives the indicium information, creates an indicium bitmap, which can be displayed on a PC monitor (not shown) and printed on the mailpiece by printer 22. PC 20 then disconnects 15 from Data Center 30 or requests another transaction. The connection between PC 20 and Data Center 30 may be through a Network Service Provider, such as on the Internet, or by direct dial using the PC's modem.

Virtual postage metering system 10 eliminates the need to maintain and account for traditional metering devices at each mailer's site and provides 20 flexibility for handling requests from multiple origins of deposit by each mailer. Virtual postage metering system 10 also provides value added services that are not available with conventional meter devices, such as, real-time address hygiene, direct marketing services and trickle charge postage payment. Virtual postage metering system 10 provides user authentication by Data Center 30 to 25 identify mailers with valid accounts. When a mailer has been authenticated for each request, for example, by a username, password or other conventional methods, Data Center 30 services the request, and returns indicium information to the PC 20 where the indicium is created and printed on the mailpiece.

Referring again to Fig. 1, the mailer initiates a postage evidencing 30 transaction by running client software in PC 20, which contacts Data Center 30. At Data Center 30, a Communication Server 32 supports connectivity from various communication technologies and protocols. The Communication Server merges all incoming traffic and routes it to a Function Server 34, which supports

mailer sign-on, postage dispensing and postal reporting. All mailer information, including use of public or private keys, is accessed from a Database Server 36 where the mailer information is securely stored using secure cryptographic processes and protocols. (It will be understood that, for security purposes, some 5 information may be stored in a secure device or location, such as the Key Management System 38.) All sensitive cryptographic processes occur in the Key Management System 38, which includes a secure, tamper-evident and tamper-responding enclosed area.

10 Mailers establish accounts through an on-line sign-up process with Data Center 30. During sign-up, the mailer enters, at PC 20, account information, such as user name, password and method of payment. Any registration fees can be charged at this time. Data Center 30, preferably administered by a meter vendor, such as Pitney Bowes Inc., arranges all meter licenses and agreements between its mailers and the Post.

15 In the preferred embodiment, the method of payment is a real-time, trickle charge, for example to the mailer's credit card, wherein the credit card is charged only for the postage dispensed for evidencing before the evidencing occurs. Alternatively, a traditional prepayment method may be used, wherein each mailer is required to put a minimum amount of money into the mailer's 20 virtual meter account. As account funds drop below a specific level a refill is charged against the mailer's account.

In previously noted U.S. Patent Application Serial Number 08/993,310, a meter (or PSD) is registered at several different post offices. The meter has internal sub-registers corresponding to each post office for which the meter is 25 authorized. The meter further has a register for the national postal service. When the customer makes a refill call, the meter reports the status of each sub-register to the refill Data Center. Funds are transferred by a refill transaction to the national postal service register. Status of the sub-registers is reported from the refill Data Center to the national postal service to allow the postal service to 30 account for postage at each local post office.

In the present invention, the PSD does not exist, i.e., there is no metering device coupled to the PC from which postage payment is requested. Virtual postage metering system 10 replaces the accounting and metering functions of

the PSD with metering software at PC 20 and mailer account information performed and updated at Data Center 30.

In accordance with the present invention, virtual postage metering system 10 provides each mailer with a metering system that has the capability of 5 originating transactions from multiple origins of deposit. In one embodiment, which is analogous to the metering system disclosed in previously noted U.S. Patent Application Serial Number 08/993,310, the PSA is registered at several different post offices and has internal sub-registers corresponding to each post office for which the PSA is authorized. When the mailer requests postage 10 evidencing from the Data Center, the Data Center determines the origin of deposit based on where the mailer originates the request for postage, or alternatively from the request itself, and, if the PSA is authorized for such origin of deposit, the Data Center completes the generation of postage evidencing and accounts for the amount of postage accordingly in the PSA and sub-register 15 corresponding to the origin of deposit.

In the preferred embodiment, there is no need for pre-authorized origins of mailing. Once the Data Center determines a valid origin of deposit based on where the mailer originates the request for postage, the Data Center completes the generation of postage evidencing and accounts for the amount of postage 20 accordingly in the PSA and sub-register corresponding to the origin of deposit. Such accounting is described in more detail below.

Various methods can be used to determine the origin of deposit for a requested transaction. For example, a method for determining origin zip code using a caller ID from a telephone call is disclosed in U.S. Patent Application 25 Serial Number 08/775,818, filed December 31, 1996, and assigned to the assignee of the present invention, which is hereby incorporated in its entirety by reference. For other types of connections (such as a network or the Internet) the origin of deposit may be determined using appropriate databases that already exist or which can be easily created (such as network ID or internet address). Of course, a mailer can enter the origin of deposit through the PC, or the Data 30 Center can determine origin of deposit from return address information provided by the mailer. However, it will be appreciated that the latter methods are less reliable.

Referring now to Fig. 2, the Database Server 36 file structure is shown. The database comprises a plurality of PSAs (postal security accounts), each PSA representing a metering account administered by Data Center 30. Each PSA has a register (RNPS) for the national Postal Service. Each PSA is also registered at up to (N) different post offices (PO<sub>1</sub>, PO<sub>2</sub>, PO<sub>N</sub>), i.e., origins of deposit. Each PSA has internal sub-registers (RPO<sub>1</sub>, RPO<sub>2</sub>, ...RPO<sub>N</sub>) corresponding to each post office for which the PSA is authorized. In the preferred embodiment of the present invention, each PSA has an RPO for each valid origin of deposit. For each postage evidencing transaction, the Data Center accounts in the RNPS of a PSA and in one of the RPO for postage evidenced. Thus, the present invention allows a request for evidence of postage to include an origin of mailing other than the origin of mailing for a master postal register of the PSA. An alternate file structure for Database Server 36, each PSA includes a national Postal Service register. However, instead of the sub-registers in each PSA, Database Server 36 has a separate account register for each origin of deposit in which real-time accounting occurs for each transaction for an origin of deposit.

The Function Server at the Data Center performs the accounting and postage evidencing generation functions and stores transaction and accounting information in the PSA and the appropriate sub-registers.

At some predetermined interval, such as daily or when the refill of the PSA occurs, Data Center 30 reports the status of PSA and each RPO to the Postal Service. In the preferred embodiment of a trickle charge method of payment, since credit card transactions have accounted for all postage payment being reported, the Postal Service verifies payment of total transactions being reported and assigns funds from such payment to the appropriate local post offices. When a prepayment method is being used, Data Center initiates the transfer of funds to the Postal Service accordingly. The mailer requests funds transferred to the RNPS register. The funds are transferred by a refill transaction to the national postal service register. Reports of the sub-registers (RPO<sub>1</sub>, RPO<sub>2</sub>, RPO<sub>N</sub>) are reported from the refill Data Center to the national Postal Service to allow the Postal Service to account for postage at each local post office. The register RNPS may have ascending and descending registers.

The RPO registers may simply be a total of postage evidenced for mail destined for the corresponding post office.

The foregoing description of the preferred embodiment of the present invention makes use of existing infrastructure of the current postal system for 5 post payment to local post offices. It will be understood that the current infrastructure could be bypassed by implementing a method for direct payments to local post offices at the time the transaction is evidenced.

When an amount of postage needed for each transaction is determined, for example, by specific request by the mailer or by automatic determination at 10 the Data Center, the amount of postage may be deducted from the mailer's PSA in a pre-payment method, added to the mailer's PSA in a post-payment method or charged directly to a pre-authorized credit card of the mailer in a real-time payment method. In the latter and preferred method, the PSA contains no funds until the time of postage evidencing at which time postage funds are present only 15 during the transaction. In this real-time payment method, funds can be transferred to the origin of deposit when the postage evidencing occurs, or preferably at a predetermined interval. Each transaction is logged to the meter database records as an historical record. It will be understood that refilling of the PSA in a prepayment method or payment in a post-payment method could be 20 completed with an automatic credit card transaction. The following description of the present invention will include the real-time payment method, however either of the pre-payment, also described below, or post-payment methods can be used with the present invention as well.

Referring now to Fig. 3, the process for distributing funds in accordance 25 with a trickle charge method of payment begins at step 200, with the mailer, through PC 20, authorizing use of a credit card account to a funds control center, such as a bank. (Such authorization may occur through the Data Center to the funds control center.) At step 205, the funds control center acknowledges such authorization and notifies Data Center 30. At step 210, the Data Center 30 activates the mailer's PSA by assigning the mailer's credit card account to it and notifies the mailer. At step 215, the mailer, through PC 20, initiates a request for indicium information from the Data Center 30, providing postal information, such as, postage amount and destination information. At step 220, Data Center 30

responds to the request by verifying sufficient funds are available, charging the mailer's credit card account, determining valid origin zip for the request, calculating a digital token or digital signature corresponding to the postal information provided with the request, and forwarding the indicium information  
5 including the digital token to PC 20. Data Center 30 also stores information relating to each transaction as a historical record to be forwarded to the Postal Service at a predetermined interval. At step 225, PC 20 obtains the indicium information from Data Center 30, generates an indicium bitmap and prints the indicium on the mailpiece. At some predetermined interval, for example daily, at  
10 step 230, Data Center 30 notifies the Postal Service of the total postage amount for each meter ID (PSA) and origin zip combination by forwarding the historical record to the Postal Service. At step 235, the Postal Service combines the transactions for each origin zip to determine the amount owed to each origin zip (local) post office. At step 240, the Postal Service assigns an appropriate  
15 amount of funds from the funds control center to each local post office. Alternatively, steps 235 and 240 could be performed at the Data Center or funds control center.)

Referring now to Fig. 4, the process for distributing funds in accordance with a prepayment version of the present invention begins at step 300, with the  
20 mailer, through PC 20, sending funds to a funds control center, such as a bank. At step 305, the funds control center acknowledges such authorization and notifies Data Center 30. At step 310, the Data Center adjusts the PSA for the mailer to account for the additional funds and notifies the mailer. At step 315, the mailer, through PC 20, initiates a request for indicium information from the  
25 Data Center 30, providing postal information, such as, postage amount and destination information. At step 320, Data Center 30 responds to the request by verifying sufficient funds are available, debiting the mailer's account, determining valid origin zip for the request, calculating a digital token or digital signature corresponding to the postal information provided with the request, and  
30 forwarding the indicium information including the digital token to PC 20. Data Center 30 also stores information relating to each transaction as a historical record to be forwarded to the Postal Service at a predetermined interval. At step 325, PC 20 obtains the indicium information from Data Center 30, generates an

- indicium bitmap and prints the indicium on the mailpiece. At some predetermined interval, for example daily, at step 330, Data Center 30 notifies the Postal Service of the total postage amount for each meter ID (PSA) and origin zip combination by forwarding the historical record to the Postal Service.
- 5 At step 335, the Postal Service combines the transactions for each origin zip to determine the amount owed to each origin zip (local) post office. At step 340, the Postal Service assigns an appropriate amount of funds from the funds control center to each local post office.

It will be understood that, although the embodiments of the present invention are described as postage metering systems, the present invention is applicable to any value metering system that includes transaction evidencing, such as monetary transactions, item transactions and information transactions. It will also be understood that, although the present invention is described with regard to origin zip codes, the present invention is suitable for any postal code utilized by various postal systems or any other postal accounting system (such as one where payment for parcels and letters are assigned to different postal departments).

While the present invention has been disclosed and described with reference to embodiments thereof, it will be apparent, as noted above, that variations and modifications may be made therein. It is, thus, intended in the following claims to cover each variation and modification that falls within the true spirit and scope of the present invention.

**What is Claimed is:**

1. A method of evidencing postage payment, the method comprising the steps of:

requesting from a local postage printing system to a remote data metering center for the generation of postage evidencing information, the request including a postage amount to be printed on a mailpiece;

determining at the remote data metering center a postal origin corresponding to the request for postage evidencing information;

first accounting at the remote data metering center for the postage amount in a general account corresponding to the local postage printing system;

second accounting at the remote data metering center for the postage amount in a payment account corresponding to the determined postal origin;

generating postage evidencing information in response to the request;

sending the postage evidencing information to the local postage printing system; and

printing the postage evidencing information on the mailpiece.

2. The method of claim 1 wherein the postage evidencing information includes the determined postal origin.

3. The method of claim 1 wherein the step of printing the postage evidencing information includes printing the determined postal origin on the mailpiece.

4. The method of claim 1 wherein the step of generating postage evidencing information comprises the step of:

generating a digital token, the digital token being encrypted information including the postage amount, associated with the mailpiece.

5. The method of claim 4 wherein the encrypted information further includes at least part of the destination address of the mailpiece and the determined postal origin.

6. The method of claim 1 wherein the steps of first accounting and second accounting comprise the steps of:

debiting the postage amount from total funds available for the general account; and

crediting the postage amount to the determined postal origin account.

7. The method of claim 1 wherein the steps of first accounting and second accounting comprise the steps of:

charging the postage amount to the general account; and

crediting the postage amount to the determined postal origin account.

8. The method of claim 1 wherein the step of determining the postal origin comprises the steps of:

receiving an originating communication from the local postage printing system requesting the postage evidencing information;

obtaining an origin identifier of the originating communication;

obtaining an address corresponding to the origin identifier; and

determining the postal origin by obtaining postal code information for the address.

9. The method of claim 8 comprising the further step of:

obtaining a meter license from the USPS based on the postal code information.

10. The method of claim 8 wherein the communication is a phone call and the identifier is a phone number and the step of obtaining the origin identifier comprises using caller ID to obtain a phone number from which the local postage printing system initiated the request for postage evidencing information.

11. The method of claim 8 wherein the communication is a network and the identifier is a network address.

12. The method of claim 1 wherein the step of determining the postal origin comprises the step of:

receiving a desired postal origin from the local postage printing system.

13. A postage metering system comprising:

a plurality of local postage printing systems, each of said local postage printing systems including a general purpose processor with an unsecured printer coupled thereto;

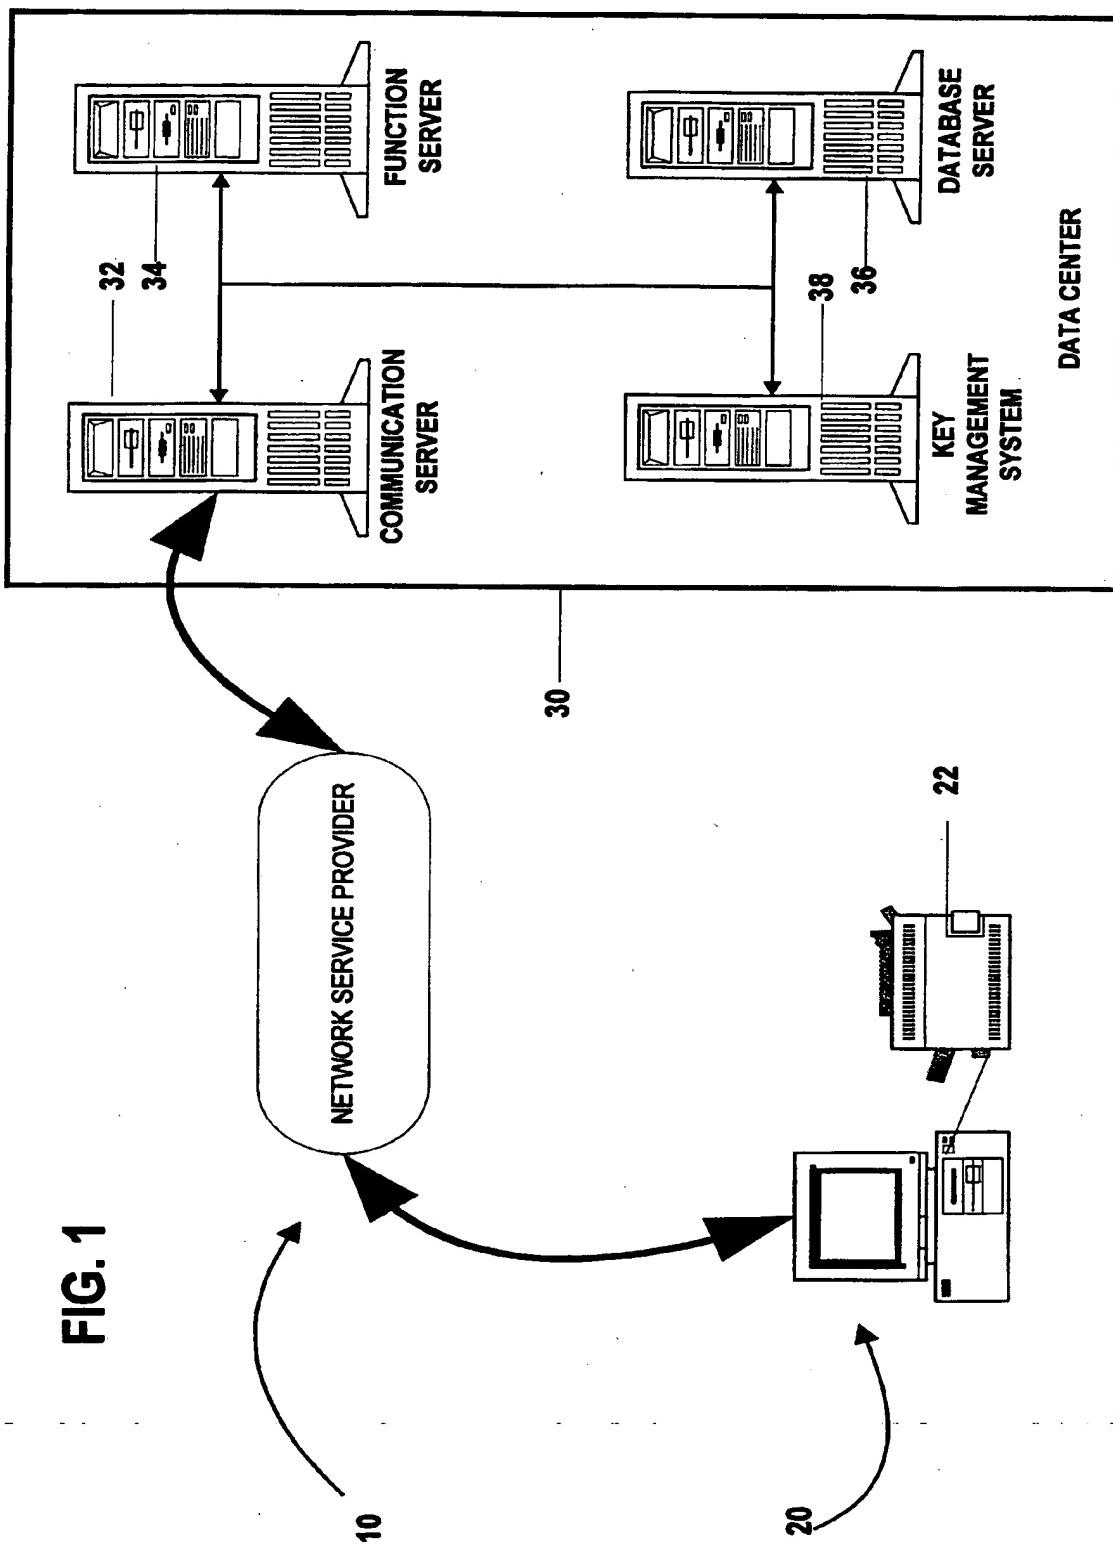

a remote data metering center communicatively coupled to the plurality of local postage printing systems, said remote data metering center including a second processor, accounting means, value storage means, encryption means and means for determining postal origin corresponding to the request for postage evidencing information, said value storage means including a general account for each of the local postage printing systems and a payment account corresponding to each determined postal origin, wherein the remote data metering center is authorized to dispense evidence of postage payment for a plurality of postal origins.

14. The system of claim 13 wherein each local postage printing system has the capability to request and obtain from the remote data metering center the evidence of postage payment to be printed on a mailpiece by the unsecure printer, the request including postage amount and destination address information.

15. The system of claim 14 wherein, for each request for evidence of postage payment, the remote data metering center determines the postal origin corresponding to said each request, generates the evidence of postage payment, debits the general account for the local postage printing system making said each request, and credits the payment account corresponding to the determined postal origin.

16. The system of claim 14 wherein, for each request for evidence of postage payment, the remote data metering center determines the postal origin corresponding to said each request, generates the evidence of postage payment, credits the general account for the local postage printing system making said each request, and credits the payment account corresponding to the determined postal origin.

17. The system of claim 13 wherein the means for determining postal origin comprises means for obtaining an address corresponding to an origin identifier associated with the request for postage evidencing information and determining the postal origin by obtaining postal code information for the address.
